What is the ideal outcome criterion in the clinical trials of patients with low back pain (LBP) in PC?

Background:
Interventions focusing on PS factors in PC → no / few clinically relevant effects
→ intervention: effective? sufficient implementation?
→ methodological choices: relevant outcome criteria?

Methods:
Litterature: clinical trials on PS factors in LBP in PC; outcome criterion for LBP.

Results (clinically relevant = patient centered):
Pain, disability, return to work, participation, care seeking, satisfaction, quality of life.

Discussion:
Which dimension(s)?
When? (repeated measures?)
What about “new” tools such as goal attainment scaling?
